Transcript

1. user (2026-07-04T00:50:47.795Z)

Code-review finder. Target: PR #62 of sports-data-collector (repo C:/Users/avidu/Projects/khelsutra-guru/sports-data-collector). Diff: `cd <repo> && gh pr diff 62`. PR branch = origin/codex/a3-golden-source-videos (read via `git show origin/codex/a3-golden-source-videos:<path>`). The PR expands data/golden_source_videos.json from 6 to 15 golden source videos (schema v1?v2, adds source_role/source_status/md5_source fields) + rewrites tests/test_golden_source_videos.py + a README line.

ANGLE ? manifest data correctness + internal consistency. Read the full data/golden_source_videos.json (via `git show origin/codex/a3-golden-source-videos:data/golden_source_videos.json`). Check:
1. **Duplicate MD5s**: the test asserts all 15 MD5s unique. Extract all 15 `md5` values and confirm no duplicates (also confirm each is exactly 32 lowercase hex).
2. **present_local vs PR-body contradiction**: the PR BODY says "GX010137 and GX010141 are recorded as `missing_local_source_hash_from_run_log`" and "13/15 entries have present local source/proxy paths". But in the JSON, ALL 15 entries (including GX010137/GX010141) have `source_status: "present_local"` (their notes say the F-drive original was found 2026-07-04). And the test asserts `source_status == "present_local"` for ALL entries. So the PR body describes a DIFFERENT state (2 missing) than the actual manifest (15 present). Is this a real body-vs-artifact inconsistency that would mislead a reviewer / a downstream consumer relying on the body?
3. **Proxy-vs-original provenance risk**: several entries are `source_role: annotation_proxy` (e.g. mahadevpura_2 = "mahadevpura-2_proxy.mp4", GX030094 = "GX030094_proxy.mp4", Boxhill_Doubles, GX020094, Badminton_BXH_2). Their md5 is the PROXY file's hash. But the README says "The indexer keys videos by file MD5... the downstream eval/training run must process the exact video file named in the manifest." If the golden eval features/labels were generated from a DIFFERENT file than the recorded proxy (e.g. the original, or a different-resolution proxy), the recorded MD5 won't match what the eval used ? a join/reproducibility break. For GX010137/GX010141 the notes explicitly say the eval-time file was a DERIVATIVE `*_1080p.mp4` with a DIFFERENT MD5 (daaf8af.../74eedbc...) than the recorded original (219a84a.../3d19ef...). So the manifest records the ORIGINAL's hash while the eval corpus may have used the 1080p derivative ? flag whether the recorded md5 is the one that actually reproduces the eval.
4. **bytes/last_write_time sanity**: any entry with implausible values (0 bytes, missing fields)?
Return up to 6 candidates as JSON [{file, line, summary, failure_scenario}]. line = line in the changed file. [] if none. Final message = only the JSON array.

2. assistant (2026-07-04T00:50:49.777Z)

I'll analyze PR #62 by examining the data and tests for data correctness and consistency issues.

@@ -104,7 +104,7 @@ python -m src.cli.curate export --sport badminton --include-staging
 ```
 The exporter writes `<out-dir>/<sport>/<video_id>.csv` (decimal-second `start,end` rows) and a
`manifest.json` pairing each CSV with its video `local_path`/`video_url`, fps, resolution, and
license. The indexer keys videos by **file MD5**, not by our `video_id`, so the downstream
eval/training run must process the exact video file named in the manifest. Flags: `--sport`
(restrict to one sport), `--include-staging` (default: curated only), `--include-noncommercial`
(default: commercial-safe only).

-The six owned golden source MP4s have a committed integrity record at
[`data/golden_source_videos.json`](data/golden_source_videos.json). It records their current
`F:` source paths, byte sizes, and full-file MD5s; uploading those large originals remains
owner-gated.
+The 15-video badminton golden eval corpus has a committed source/proxy integrity record at
[`data/golden_source_videos.json`](data/golden_source_videos.json). It records current local
source paths, byte sizes, and full-file MD5s; uploading those large originals/proxies remains
owner-gated.

```

8. assistant (2026-07-04T00:50:59.349Z)

Now let me check the PR description to understand the stated changes:

9. user (2026-07-04T00:51:01.370Z)

Summary

- Expands `data/golden_source_videos.json` from the original six owned golden videos to the full 15-video badminton golden eval corpus used by `badminton-highlight-indexer/output/human_lovo_manifest.json`.
- Bumps the manifest schema to v2 with explicit `source_role`, `source_status`, and `md5_source` fields so annotation proxies and run-log-only source hashes are represented honestly.
- Updates the manifest contract test to require all 15 eval IDs, unique 32-char MD5s, and continued DB path reconciliation for the original six collector-registered videos.

Provenance notes

- 13/15 entries have present local source/proxy paths and file hashes from `Get-FileHash -Algorithm MD5`.
- `GX010137` and `GX010141` are recorded as `missing_local_source_hash_from_run_log`: their

Boxhill run logs record source inputs `GX010137_1080p.mp4` and `GX010141_1080p.mp4` plus the full-file hash emitted as `video_id`, but those exact source files were not present in the synced local/Drive paths on 2026-07-04.
- Upload remains owner-gated; this PR records source identity/provenance and does not upload video bytes.

Validation
- `python -m pytest tests\test_golden_source_videos.py` -> 2 passed
- `ruff check tests\test_golden_source_videos.py` -> passed
- `python -m json.tool data\golden_source_videos.json` -> passed
- `ruff check .` -> passed
- `python -m pytest` -> 295 passed, 2 skipped

10. assistant (2026-07-04T00:51:25.443Z)

Now I have all the information I need. Let me analyze for the four issues:

Analysis:

1. **Duplicate MD5s**: Extracting all 15 MD5s from the JSON:
   - 751b6266be89dce2e9a39946caa9325c
   - 1f8ab4ba3eea45fe43a14366f825fc2f
   - 25b29aa56ba69b7e34e35d811309bba2
   - d50da42b59dae2fdeec03e47f3b35536
   - 8fe6b719603dd7a7b2b6ef543139a4a3
   - 915473794e0909c9f95a01e4511a5e98
   - d75f66340a44cac37357cce9ab988724
   - db84f3e65318e49aea8320de4c44f7d1
   - 38bef75d78cbbd8209a80fd73c28e6ed
   - 27f1c707bbfb9b81d3b7c6b5afdda7e8
   - ebebccb702c4be5f3a7da7e000b0f3a4
   - 219a84a4e1a985edf5fb039142c18b8d
   - 3d19ef835a69be93acdd75ef636f345a
   - 9a35fffdfbdee397575ffda9d68ebca3
   - 08471270f285123021ef4f9d21d1b05b

   All 15 are unique and valid 32-char lowercase hex. ? No issue.

2. **PR body vs JSON contradiction**: The PR body states "GX010137 and GX010141 are recorded as `missing_local_source_hash_from_run_log`" but in the actual JSON:
   - Both entries have `source_status: "present_local"` (not missing)
   - Both have `source_role: "owned_original"` (not a run-log status)
   - Both have `local_path` pointing to F-drive paths that were "found after the drive was connected on 2026-07-04"
   - The notes explain the F-drive original was found and that earlier Boxhill run logs recorded different derivative files with different MD5s

   This is a critical body-vs-artifact inconsistency. The PR body describes a state where GX010137/GX010141 are "missing from run log" (implying unavailable), but the actual JSON records them as present_local with complete file hashes. This contradicts reviewer expectations and could mislead downstream consumers. **FINDING #1**

3. **Proxy-vs-original provenance risk**: Several entries use `annotation_proxy` or `annotation_source` roles. For example:
   - `mahadevpura_2` (annotation_proxy): filename is "mahadevpura-2_proxy.mp4", MD5 is the proxy's hash (d75f66340a44cac37357cce9ab988724)
   - `GX030094` (annotation_proxy): filename is "GX030094_proxy.mp4", MD5 is the proxy's hash (27f1c707bbfb9b81d3b7c6b5afdda7e8)
   - `Badminton_BXH_2` (annotation_proxy): filename is "Badminton BXH 2_proxy.mp4", MD5 is the proxy's hash (ebebccb702c4be5f3a7da7e000b0f3a4)
   - `GX020094` (annotation_proxy): filename is "GX020094_proxy.mp4", MD5 is the proxy's hash (08471270f285123021ef4f9d21d1b05b)
   - `Boxhill_Doubles` (annotation_proxy): filename is "Boxhill Doubles_proxy.mp4", MD5 is the proxy's hash (9a35fffdfbdee397575ffda9d68ebca3)

The README states: "the indexer keys videos by file MD5... the downstream eval/training run must process the exact video file named in the manifest." If the eval features/labels were computed from a different video file (original vs proxy, or different resolution), the recorded MD5 won't match what the eval used ? reproducibility break. **The manifest doesn't document whether the recorded MD5 is the file that was actually used for eval, or a different version.** **FINDING #2**

4. **GX010137/GX010141 MD5 mismatch with eval corpus**: The notes explicitly state:
   - GX010141: "Earlier Boxhill run log records derivative GX010141_1080p.mp4 with MD5 daaf8af198640516d14b217f50445d99; this entry records the present original source file."
   - GX010137: "Earlier Boxhill run log records derivative GX010137_1080p.mp4 with MD5 74eedbc35d739c231344b8929df4b4a7; this entry records the present original source file."

   The manifest records the ORIGINAL file's MD5 (219a84a4.../3d19ef83...), but the eval corpus may have used the 1080p derivative with different MD5s (daaf8af.../74eedbc...). If downstream eval/training runs try to match by MD5, they will not find these files under the recorded hashes. **FINDING #3**

5. **Bytes/last_write_time sanity**: All bytes values are > 0, all last_write_time fields are present and formatted. No implausible values detected. ? No issue.
