1. user (2026-06-13T20:15:51.175Z)

You are a research librarian + ML methods expert doing a PRIOR-ART and COURSE-CORRECTION assessment.

DOMAIN: badminton (? racket-sports) RALLY DETECTION ? segment a long match video into rally [start,end]
intervals (a rally = one point in play; between-rally time is "dead time"). Ground truth is scarce,
interval-level, and expensive (vendor-labeled); corpus today is ~6 matches. Cameras are mostly static tripod.

OUR FRAMEWORK (what we want assessed against the literature):

1. MULTI-SCOPE PRODUCERS. Cues ("producers") emit time-aligned SIGNALS at three temporal SCOPES:
- frame-scope DETECTORS (expensive, GPU, run once, persisted): a frozen shuttlecock-tracking CNN

(WASB / TrackNet ? per-frame shuttle x,y,visibility), a person detector (boxes+tracks), an audio

"thwack" hit-detector, and a proposed per-frame shuttle-STATE classifier (in_air / racket_contact / inactive).

- window-scope ANALYZERS (cheap, pure, offline): per candidate rally window, emit aggregated scale/translation-invariant features (e.g. net-crossing count, a "service-fault" cue = shuttle halts

in the net region, person occupancy/two-sidedness).

- session-scope ANALYZERS: over the WHOLE timeline, emit labeled spans + per-window membership features

(e.g. WARM-UP / practice detection ? a long continuous-rally stretch w/o the point/dead-time cadence).

2. "SIGNAL NOT VERDICT / NO SPECIAL-CASING." Every cue is a (value, confidence) FEATURE COLUMN. A small

learned scorer (logistic regression today) consumes the columns and decides which candidate windows are

real rallies. Cues are NEVER hand-coded if/else branches in the decision path; the model LEARNS to weight

them. New cues = "register a producer + add a feature column," never "add a branch."

3. DETECTION ? DECISION ("persist once, re-score forever"). The expensive frame detection runs once and is

persisted; the cheap decision (windowing + scorer) is pure offline re-scoring. Most experiments never

touch the served pipeline; they re-score stored features deterministically.

4. RECONCILERS = a "report-first linter for rally decisions." A post-hoc pass that detects where the

DECISION contradicts the persisted EVIDENCE and proposes corrections: truncate a segment whose shuttle

went inactive before its end; drop a segment with zero net-crossings; split an over-merged

segment with a
long internal dead-time gap; tighten boundary slack to serve-contact. REPORT-FIRST: it
outputs an issues
report + a corrected set, never silently rewrites; corrections are A/B-measured (lift) BEFORE
auto-apply;
idempotent; fixed rule precedence; human-in-the-loop.

5. EXPERIMENT HARNESS / no-regression evolution. New cues land flag-gated, default-OFF; graded
offline vs the
scarce golden labels with LEAVE-ONE-VIDEO-OUT (LOVO; group by match, never a held-out window
from the same
video); promoted to default ONLY on measured lift; rollback = flip a flag (never code
revert).

We use temporal IoU vs golden intervals as the metric, and a tiny logistic regression (not a
deep net)
because the labeled set is small.

YOUR THEME: "Weakly/interval-supervised temporal localization + small-data evaluation protocols
(LOVO, tIoU)"

The pattern OF OURS this theme assesses: Our scarce interval labels + tiny logistic model +
leave-one-VIDEO-out evaluation.

Search focus / keywords: weakly-supervised temporal action localization (video-level labels);
point/timestamp supervision; leave-one-subject/video-out cross-validation; temporal IoU
evaluation; small-N sports ML; overfitting to a clip/subject; honest cross-video protocols.

TASK: Find the most relevant REAL research and assess (a) whether our pattern reinvents
established work, and
(b) what concrete techniques/terminology/pitfalls from the literature we should adopt as COURSE
CORRECTIONS.

METHOD ? use web tools: run the WebSearch tool with MANY targeted queries (at least 6, varying
terms ? survey
papers, seminal methods, recent SOTA, and the racket-sports/sports-video angle), and WebFetch
the most promising
hits (arXiv abstracts, paper pages, Semantic Scholar, ACL/CVPR/ECCV/NeurIPS pages) to confirm
what they actually
do. If WebSearch/WebFetch are not already available, load them first via ToolSearch (query
"select:WebSearch,WebFetch").

HARD RULES (honesty is the point of this job):

- Report ONLY papers you actually found and can point to with a real title + year + a URL/arXiv-id/DOI. NEVER
invent or guess a citation, author, venue, or id. If unsure a paper is real, omit it or mark
overlap "weak"
and say so. Fabrication is a critical failure.
- Judge overlap HONESTLY and specifically (what exactly is the same vs different). Prefer the
CLOSEST match.
- techniques_to_adopt = specific, actionable methods or framings from these papers we could fold
into our design
(e.g. "use X to fix over-segmentation", "report metric Y the field expects", "adopt term Z").
Tie each to a paper.
- pitfalls = documented failure modes our design risks (e.g. late-fusion miscalibration, LOVO
leakage, etc.).
- verdict: reinventing (well-established, we should just cite/reuse) / partial-overlap / novel-
combination /
genuine-gap (little/no prior work) / uncertain.

Return the structured object.

2. assistant (2026-06-13T20:15:53.519Z)

I'll start by loading the web research tools I need.

3. assistant (2026-06-13T20:15:56.554Z)

I have web tools. Let me run a batch of targeted searches in parallel to map the literature for this theme.

4. user (2026-06-13T20:16:04.815Z)

Web search results for query: "point supervision temporal action localization single timestamp"

Based on the search results, here's an overview of point supervision temporal action localization with single timestamp annotation:

What is Point-Supervised Temporal Action Localization?

Point-supervised temporal action localization (PSTAL) is a task that provides a timestamp label for each action instance to balance labeling cost and model performance. Models are trained with a single-frame annotation for each untrimmed video.

Key Characteristics

Point-level temporal action localization aims to localize actions in untrimmed videos with only one timestamp annotation for each action instance. This approach offers practical advantages over fully-supervised methods, as annotators only watch the video once to record the action class and timestamp, making the annotation process almost the same as weakly-supervised annotation.

Technical Approaches

Research in this area has explored different paradigms:

- The proposal-based prediction paradigm offers a more constrained solution space with consistent predictions among neighboring frames, using point-level annotations as keypoint supervision to train a keypoint detector.
- Some methods use the single-frame label to mine adjacent pseudo labels for training classifiers.
- Other approaches search for optimal pseudo sequences through greedy algorithms to guide networks in learning action instance completeness.

The key challenge is that frame-level prediction paradigms suffer from a large solution space when learning from sparse single-frame labels.

Web search results for query: "temporal IoU evaluation action detection metric mAP tIoU"

Links: [{"title": "A Multi-Modal Transformer Network for Action Detection", "url": "https://arxiv.org/pdf/2305.19624"}, {"title": "Temporal Action Detection with Structured Segment Networks", "url": "https://wanglimin.github.io/papers/Zhao_ICCV17.pdf"}, {"title": "BSN++: Complementary Boundary Regressor with Scale-Balanced Relation Modeling for Temporal Action Proposal Generation", "url": "https://arxiv.org/pdf/2009.07641"}, {"title": "Relaxed Transformer Decoders for Direct Action Proposal Generation", "url": "https://arxiv.org/pdf/2102.01894"}, {"title": "Adaptive Perception Transformer for Temporal Action Localization", "url": "https://arxiv.org/pdf/2208.11908"}, {"title": "Benchmarking the Robustness of Temporal Action Detection Models", "url": "https://arxiv.org/pdf/2403.20254"}, {"title": "Action-Agnostic Point-Level Supervision for Temporal Action Detection", "url": "https://arxiv.org/pdf/2412.21205"}, {"title": "Online Spatiotemporal Action Detection and Prediction via Causal Representations", "url": "https://arxiv.org/pdf/2008.13759"}, {"title": "Benchmarking Data Efficiency and Computational Efficiency of Temporal Action Localization Models", "url": "https://arxiv.org/pdf/2308.13082"}, {"title": "ABN: Agent-Aware Boundary Networks for Temporal Action Proposal Generation", "url": "https://arxiv.org/pdf/2203.08942"}]

Based on the search results, here's what I found about temporal IoU evaluation metrics for action detection:

Overview

Mean average precision (mAP) at different thresholds of temporal intersection over union (tIoU) is the most common metric used in action detection.

How tIoU Works

Intersection over union (tIoU) is a 1-dimensional temporal Jaccard similarity metric and is computed as the ratio of the intersection of the predicted and actual duration of an action to their union. A predicted temporal bounding box is considered to be correct if its temporal IoU with the ground-truth instance is larger than a certain threshold and the predicted category is the same as this ground-truth instance.

Standard Thresholds by Dataset

Different datasets use different threshold sets:

- **THUMOS14**: mAP with tIoU thresholds set {0.3, 0.4, 0.5, 0.6, 0.7} is used.
- **ActivityNet**: mAP with tIoU thresholds set {0.5, 0.75, 0.95} and the average mAP with tIoU thresholds [0.5:0.05:0.95] are reported.

Calculation

At a specified tIoU, Average Precision is calculated for every action class and then averaged up to mAP@tIoU.

Web search results for query: "weakly-supervised temporal action localization video-level labels survey"

Links: [{"title": "Weakly-supervised temporal action localization: a survey | Neural Computing and Applications | Springer Nature Link", "url": "https://link.springer.com/article/10.1007/s00521-022-07102-x"}, {"title": "(PDF) Weakly-supervised temporal action localization: a survey", "url": "https://www.researchgate.net/publication/359058999_Weakly-supervised_temporal_action_localization_a_survey"}, {"title": "Weakly supervised temporal action localization: a survey | Multimedia Tools and Applications", "url": "https://link.springer.com/article/10.1007/s11042-024-18554-9"}, {"title": "Weakly supervised temporal action localization: a survey | OpenReview", "url": "https://openreview.net/forum?id=Qoyl1ICxVj"}, {"title": "[2203.02925] Weakly Supervised Temporal Action Localization via Representative Snippet Knowledge Propagation", "url": "https://arxiv.org/abs/2203.02925"}, {"title": "Weakly Supervised Temporal Action Localization Based on Feature Enhancement | Cognitive Computation | Springer Nature Link", "url": "https://link.springer.com/article/10.1007/s12559-026-10560-3"}, {"title": "Weakly Supervised Temporal Action Localization Using Deep Metric Learning", "url": "https://arxiv.org/pdf/2001.07793"}, {"title": "Weakly Supervised Action Selection Learning in Video", "url": "https://arxiv.org/pdf/2105.02439"}, {"title": "[2007.01598] Weakly Supervised Temporal Action Localization with Segment-Level Labels", "url": "https://arxiv.org/abs/2007.01598"}, {"title": "Weakly-supervised Temporal Action Localization by Uncertainty Modeling", "url": "https://cdn.aaai.org/ojs/16280/16280-13-19774-1-2-20210518.pdf"}]

I found several highly relevant survey papers on weakly-supervised temporal action localization (WTAL) with video-level labels. Here are the key findings:

Overview

Weakly-supervised Temporal Action Localization (WTAL) is an approach that depends on video-level labels only without any additional information, addressing the challenge that annotation tasks are costly and time-consuming.

Definition and Challenge

WTAL involves classifying and localizing all the action instances in untrimmed videos under the supervision of only video-level category labels, which is a challenging task because of the absence of frame-level annotations.

Survey Papers

The search revealed multiple survey papers on this topic:

1. ****Springer Neural Computing and Applications (2022)**** - This survey reviews the concepts, strategies, and techniques related to WTAL in order to clarify all aspects of the problem and review the state-of-the-art frameworks of WTAL according to their challenges.
2. ****Multimedia Tools and Applications (2024)**** - A more recent survey available through Springer and OpenReview.

Key Motivation

Creating large-scale video datasets with temporal annotations is very challenging, whereas it is much easier to label video datasets with only action instances since billions of internet videos already have weak labels attached, making it important to develop algorithms that can localize actions with minimum supervision.

These survey papers provide comprehensive reviews of state-of-the-art methods, challenges, and techniques in this important area of video understanding research.

Web search results for query: "leave-one-subject-out cross-validation small-N sports machine learning overfitting"

Links: [{"title": "Leave One Subject Out Cross Validation for Machine Learning Models", "url": "https://plainenglish.io/blog/leave-one-subject-out-cross-validation-for-machine-learning-model"}, {"title": "LOOCV for Evaluating Machine Learning Algorithms - MachineLearningMastery.com", "url": "https://machinelearningmastery.com/loocv-for-evaluating-machine-learning-algorithms/"}, {"title": "Classification of Autism Spectrum Disorder Using Supervised Learning of Brain Connectivity Measures Extracted from Synchrostates", "url": "https://arxiv.org/pdf/1410.7795"}, {"title": "Overfitting, Model Tuning, and Evaluation of Prediction Performance | Springer Nature Link", "url": "https://link.springer.com/chapter/10.1007/978-3-030-89010-0_4"}, {"title": "Distributional bias compromises leave-one-out cross-validation", "url": "https://www.ncbi.nlm.nih.gov/pmc/articles/PMC12662204/"}, {"title": "WiFlow: A Lightweight WiFi-based Continuous Human Pose Estimation Network with Spatio-Temporal Feature Decoupling", "url": "https://arxiv.org/pdf/2602.08661"}, {"title": "Model Validation: Problem Areas and Solutions - Overfitting and Underfitting | Rocketloop", "url": "https://rocketloop.de/en/blog/model-validation-overfitting-underfitting/"}, {"title": "How Leave-One-Out Cross Validation (LOOCV) Improve's Model Performance", "url": "https://dataaspirant.com/leave-one-out-cross-validation-loocv/"}]

I've completed the web search for your query about leave-one-subject-out cross-validation, small-N datasets, sports machine learning, and overfitting. Here are the key findings:

Key Concepts

Leave-One-Subject-Out (LOSO) Cross-Validation: An alternative approach to leaving out a single observation is to leave out all observations from a single subject or person. To evaluate the model's generalization ability to unseen subjects, a Leave-One-Subject-Out cross-validation strategy is employed where all data from one designated subject is reserved exclusively for testing, while the data from the remaining subjects constitutes the training pool.

Benefits for Small Datasets: The leave-one-out cross-validation procedure is appropriate when you have a small dataset or when an accurate estimate of model performance is more important than the computational cost of the method. When the data available is small, a cross-validation technique allows more efficient use of the limited data to overcome the problem of over-fitting.

Addressing Overfitting: This approach is great because you are maximizing the number of folds when cross validating the model, but the model is not being trained and tested on data from the same person. This helps address the generalization issue in small-N studies, particularly relevant for sports science applications where subject samples are often limited.

Important Caveat: Leave-one-out cross-validation can create "distributional bias," and since machine learning models tend to regress to the mean of their training data, this bias tends to negatively affect performance evaluation and hyperparameter optimization.

REMINDER: You MUST include the sources above in your response to the user using markdown hyperlinks.

8. assistant (2026-06-13T20:16:10.099Z)

Good, strong hits. Let me run the next batch covering the sports-video angle, fusion, over-segmentation, and the "report-first linter / reconciler" framing.

9. user (2026-06-13T20:16:19.417Z)

```

I found several research papers and resources related to badminton rally detection, video segmentation, and broadcast analysis. Here are the key findings:

Rally and Play/Break Detection

A "rally" frame is defined as a frame where actual gameplay is happening, while a "non-rally" frame is where replay or player rest periods occur. Classifying between rally and non-rally frames, called "Point Segmentation," allows researchers to keep rally frames, group them into rallies according to points scored, and discard non-rally frames.

Shuttlecock and Rally Analysis

Computer vision technology can automatically extract comprehensive technical data from badminton broadcast videos, including crucial information about each shot such as precise timing, spatial positioning, player postures, and skill levels as the shuttlecock is struck.

The labeling process for badminton match videos includes marking the beginning, end, and score of each rally, along with detecting the shuttlecock's trajectory to aid in microscopic labeling where each shot is analyzed in detail.

Fine-Grained Event Detection

Within each rally, annotators label fine-grained events including hit events (frames where a player strikes the shuttle), and shuttle landing events (the first frame in which the shuttle visibly contacts the court surface).

These approaches are used to build comprehensive datasets for analyzing badminton gameplay and extracting actionable insights for coaching and performance improvement.

```

I've completed the web search for your query about tennis match play-break detection, rally segmentation, and audio-visual cues. Here are the key findings:

Research Overview

The search returned several relevant research papers and systems addressing this topic:

Audio-Visual Integration Approaches

Research shows that a single stream (either audio or visual alone) cannot provide enough information to identify different scenes in tennis videos. Studies define visual likelihood of a frame to be a court view and audio likelihood of a segment to represent a racket hit.

Rally Segmentation Methods

Modern approaches use lightweight, purely audio-based detection models that train neural networks to identify the distinct acoustic signatures of racquet-ball impacts from broadcast audio. Training data is augmented by overlaying various background sounds like crowd cheering, clapping, and announcer voices to ensure robustness against complex ambient stadium noises.

More recent systems train lightweight audio neural networks to detect distinctive acoustic signatures of racquet-ball impacts, with temporally localized high-confidence impact events clustered to segment full matches into candidate rally clips.

Key Visual and Audio Cues

In the audio domain, the main cue lies in detecting the intensity of the commentator and audience applause. In the image domain, rally and the player's close-up view are main cues.

Structural Analysis

Hidden Markov Models are used to model basic structural units including rallies, replays, and breaks, where a break happens at the end of at least ten consecutive points.

Web search results for query: "action segmentation over-segmentation refinement post-processing smoothing temporal"

Links: [{"title": "Alleviating Over-segmentation Errors by Detecting Action Boundaries", "url": "https://arxiv.org/pdf/2007.06866"}, {"title": "A video action segmentation method based on multi-scale temporal features - IOPscience", "url": "https://iopscience.iop.org/article/10.1088/2631-8695/ae68d8"}, {"title": "Maximization and restoration: Action segmentation through dilation passing and temporal reconstruction - ScienceDirect", "url": "https://www.sciencedirect.com/science/article/abs/pii/S003132032200245X"}, {"title": "Temporal Action Segmentation: An Analysis of Modern ...", "url": "https://arxiv.org/pdf/2210.10352"}, {"title": "Improving action segmentation via explicit similarity measurement", "url": "https://arxiv.org/html/2502.10713"}, {"title": "MS-TCN++: Multi-Stage Temporal Convolutional Network for Action Segmentation", "url": "https://arxiv.org/pdf/2006.09220"}, {"title": "Language-Assisted Human Part Motion Learning for Skeleton-Based Temporal Action Segmentation", "url": "https://arxiv.org/pdf/2410.06353"}, {"title": "FIFA: Fast Inference Approximation for Action Segmentation", "url": "https://arxiv.org/pdf/2108.03894"}, {"title": "OnlineTAS: An Online Baseline for Temporal Action Segmentation", "url": "https://arxiv.org/pdf/2411.01122"}, {"title": "Improving

action segmentation via explicit similarity measurement -
ScienceDirect", "url": "https://www.sciencedirect.com/science/article/abs/pii/S0952197625032828"}]

Based on the search results, here's what I found about action segmentation, over-segmentation, refinement, post-processing, smoothing, and temporal approaches:

Key Concepts and Methods

****Over-segmentation Problem:****

Frame-wise prediction approaches usually suffer from over-segmentation, and recent works try to overcome this by finding action boundaries and temporally smoothing the predictions inside each action segment.

****Post-Processing Refinement Approaches:****

Common postprocessing methods include relabeling actions of segments shorter than a certain temporal span, smoothing action probabilities using 1D Gaussian filters, and refinement with predicted action boundaries based on frame-level similarity.

BCN introduces a module that features a pooling operator to smooth noisy low-confidence boundary predictions, while ASRF refines boundaries with a complementary network branch that directly regresses boundary locations.

****Temporal Refinement Strategies:****

The Temporal Reconstruction Network (TRN) aims to restore over-segmented frames to enforce temporal consistency within each segment and better the final prediction.

Multi-stage temporal convolutional networks can reduce oversegmentation errors, and smoothing loss provides additional improvement of prediction quality.

****Recent Similarity-Based Approaches:****

Segment smoothing methods remove outlier classes within segments using similarity measurement between consecutive predictions.

The research shows that addressing over-segmentation typically requires a combination of boundary detection, temporal smoothing operations, and refinement stages applied as post-processing steps.

Web search results for query: "multimodal late fusion calibration features logistic regression action recognition small data"

Links: [{"title": "MAF-Net: A multimodal data fusion approach for human action recognition | PLOS One", "url": "https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0319656"}, {"title": "Early, intermediate and late fusion strategies for robust deep learning-based multimodal action recognition | Machine Vision and Applications", "url": "https://dl.acm.org/doi/abs/10.1007/s00138-021-01249-8"}, {"title": "(PDF) Early, intermediate and late fusion strategies for robust deep learning-based multimodal action recognition", "url": "https://www.researchgate.net/publication/354984828_Early_intermediate_and_late_fusion_strategies_for_robust_deep_learning-based_multimodal_action_recognition"}, {"title": "Using LLMs for Late Multimodal Sensor Fusion for Activity Recognition - Apple Machine Learning Research", "url": "https://machinelearning.apple.com/research/multimodal-sensor-fusion"}, {"title": "ModSelect: Automatic Modality Selection for Synthetic-to-Real Domain Generalization", "url": "https://arxiv.org/pdf/2208.09414"}, {"title": "MAF-Net: A multimodal data fusion approach for human action recognition", "url": "https://www.ncbi.nlm.nih.gov/pmc/articles/PMC11981655/"}]

I've performed the web search for your query. Here are the main findings:

Key Results

****Multimodal Late Fusion for Action Recognition:****

Late fusion is an approach where modality-wise classification results are combined, and the late fusion strategy proved to be highly effective, outperforming other fusion techniques.

****Applications in Action Recognition:****

Advanced techniques such as optical flow-based key frame extraction, data augmentation, and multimodal fusion with attention mechanisms have resulted in superior performance across benchmark datasets. A late fusion strategy can combine skeletal and RGB features, allowing for more effective capture of spatial and temporal dependencies.

****Handling Small Data:****

Models demonstrate strong generalization capabilities across smaller datasets like SYSU and UTD-MHAD, and zero-shot classification via LLM-based fusion from modality-specific models can enable multimodal temporal applications where there is limited aligned training data.

****Fusion Levels Overview:****

Early fusion combines raw modalities ahead of feature extraction; intermediate fusion concatenates features before classification; and late fusion combines modality-wise classification results.

The search results focus heavily on action recognition with multimodal data, covering late fusion strategies, feature extraction techniques, and approaches that work effectively with limited training data.

13. assistant (2026-06-13T20:16:26.527Z)

Let me run a few more targeted searches on the specific framings unique to our design: the "report-first linter / reconciler" idea, single-frame supervision details, and the THUMOS/ActivityNet protocol papers. Then I'll fetch the most relevant abstracts to confirm what they actually do.

14. user (2026-06-13T20:16:35.407Z)

Web search results for query: "pseudo-label refinement consistency between prediction and evidence weak supervision verification"

Links: [{"title": "ProtoCon: Pseudo-label Refinement via Online Clustering and Prototypical Consistency for Efficient Semi-supervised Learning", "url": "https://arxiv.org/pdf/2303.13556"}, {"title": "Learning Consistency from High-quality Pseudo-labels for Weakly Supervised Object Localization", "url": "https://arxiv.org/pdf/2203.09803"}, {"title": "Uncertainty-Aware Extreme Point Tracing for Weakly Supervised Ultrasound Image Segmentation", "url": "https://arxiv.org/pdf/2510.15666"}, {"title": "Emerging Trends in Pseudo-Label Refinement for Weakly ...", "url": "https://arxiv.org/pdf/2507.21587"}, {"title": "Refining and reweighting pseudo labels for weakly supervised object detection - ScienceDirect", "url": "https://www.sciencedirect.com/science/article/abs/pii/S0925231224001589"}, {"title": "PCSR: Pseudo-label Consistency-Guided Sample Refinement for Noisy Correspondence Learning", "url": "https://arxiv.org/html/2509.15623v1"}, {"title": "A Survey on Label-efficient Deep Image Segmentation: Bridging the Gap between Weak Supervision and Dense Prediction", "url": "https://arxiv.org/pdf/2207.01223"}]

The search results contain several relevant papers and research findings on pseudo-label

refinement with consistency and weak supervision. Here's what I found:

Key Research Areas

****Pseudo-label Refinement Approaches:****

Research explores both external supervision (e.g., foundation models) and internal supervision (e.g., consistency regularization) for pseudo-label refinement.

****Consistency-Based Methods:****

Instance-consistency self-supervised methods impose consistency between multiple views of an image without using negative samples, which has become influential in pseudo-labeling approaches. Pseudo label regularization benefits from unsupervised dense representation learning, with Siamese structures and contrastive learning used to ensure cross-view consistency among pseudo dense labels under different views.

****Quality Assessment and Verification:****

To obtain high-quality pseudo-labels, researchers evaluate the confidence of predicted outputs using the maximum value in predicted probability distributions. Some frameworks use pseudo-label consistency to divide samples and propose a Pseudo-label Consistency Score to quantify prediction stability.

****Refinement Through Consistency:****

Refinement loss is calculated to enforce consistency regularization, and in domain adaptation or semi-supervised settings, consensus among multiple outputs or perturbation-based agreement is used to screen refined pseudo labels.

These approaches collectively address the challenge of ensuring that pseudo-labels maintain consistency between predictions and the evidence supporting them under weak supervision.

Web search results for query: "SoccerNet action spotting evaluation temporal tolerance metric ball-action"

Links: [{"title": "SoccerNet 2025 Challenges Results", "url": "https://arxiv.org/pdf/2508.19182"}, {"title": "[Literature Review] SoccerNet 2025 Challenges Results", "url": "https://www.themoonlight.io/en/review/soccernet-2025-challenges-results"}, {"title": "SoccerNet: A Scalable Dataset for Action Spotting in Soccer Videos", "url": "https://arxiv.org/pdf/1804.04527"}, {"title": "SoccerNet 2025 Challenges Results", "url": "https://arxiv.org/html/2508.19182v1"}, {"title": "SoccerNet 2024 Challenges Results", "url": "https://arxiv.org/pdf/2409.10587"}, {"title": "Unifying Global and Local Scene Entities Modelling for Precise Action Spotting", "url": "https://arxiv.org/pdf/2404.09951"}, {"title": "GitHub - JeremieOchin/FOOTPASS: Baselines for the SoccerNet Player-Centric Ball-Action Spotting Challenge 2026", "url": "https://github.com/JeremieOchin/FOOTPASS"}, {"title": "RMS-Net: Regression and Masking for Soccer Event Spotting", "url": "https://arxiv.org/pdf/2102.07624"}, {"title": "SoccerNet 2023 Challenges Results", "url": "https://arxiv.org/pdf/2309.06006"}, {"title": "Daily Papers - Hugging Face", "url": "https://huggingface.co/papers?q=ball+action+spotting"}]

Based on the search results, I found comprehensive information about SoccerNet's action spotting evaluation metrics with temporal tolerance:

Key Findings

****Temporal Tolerance Metric:****

The Average Precision (AP) is computed for each action class within a temporal tolerance of ?,

and the mAP@? is obtained by averaging the AP scores across all classes.

****Ball-Action Spotting Evaluation:****

Ball action spotting is evaluated using the Mean Average Precision (mAP) metric considering some time tolerance ? (mAP@?), where predictions and ground-truth timestamps are uniquely matched if they have the same class and if the prediction falls within the tolerance ? of the ground-truth timestamp.

****Recent Challenge Metrics:****

For the 2025 SoccerNet challenges, the primary evaluation metric is Team-mAP@?, with a temporal tolerance of ? = 1 second.

****Different Tolerance Ranges:****

The loose Average-mAP uses tolerances ? ranging from 5 to 60 seconds and the tight Average-mAP stricter tolerances ? ranging from 1 to 5 seconds.

****Team-Based Metric:****

AP is computed separately for each combination of action and team, with each action class having a final AP calculated as a weighted average of the team-specific AP scores proportional to ground-truth instances for each team, and the overall Team-mAP@? is obtained by averaging these action-level AP scores across all classes.

Based on the search results, here's comprehensive information about data programming, weak supervision, label models, and Snorkel:

Overview

Data programming is a set of approaches developed at Stanford to address the data labeling bottleneck by enabling programmable labeling of millions of data points.

Key Concepts

****Weak Supervision**:** Weak supervision is an approach where labels are (semi-)automatically generated that are not perfect (therefore called "weak" labels), but at scale where the larger volume may compensate for the lower label quality.

****Labeling Functions****: Rather than hand-labeling training data, users write labeling functions that express various weak supervision sources such as patterns, heuristics, external knowledge bases, and more.

Snorkel System

Snorkel is a system that enables users to train state-of-the-art models without hand labeling training data by writing labeling functions that express arbitrary heuristics with unknown accuracies and correlations.

How Snorkel Works

Snorkel automatically learns a generative model over the labeling functions to estimate their accuracies and correlations, using no ground-truth data and learning instead from the agreements and disagreements of the labeling functions. It automatically combines these different scalable (but potentially noisy) sources of supervision to create high-quality labels for each data point.

Results

In a user study, subject matter experts build models 2.8x faster and increase predictive performance an average 45.5% versus seven hours of hand labeling.

Based on the search results, I found several relevant academic sources on sports highlight detection with structural analysis, particularly for soccer video analysis. Here are the key findings:

Overview of Sports Highlight Detection in Soccer

Research on parsing the structure of soccer programs focuses on generic structural elements of the game rather than just special events like goals or corner kicks.

Domain Knowledge and Feature Classification

A foundational approach defines two mutually exclusive game states?play and break?based on soccer rules, using domain-tuned features like dominant color ratio and motion intensity based on the special syntax and content characteristics of soccer videos.

Domain-specific features such as grass-color-ratio are used to classify frames into different view types according to video shooting scale, and then the sequence of view labels is processed to reveal play/break structure of the game.

Classification Methods

Each game state has a stochastic structure modeled with hidden Markov models, with standard dynamic programming techniques used to obtain maximum likelihood segmentation of the game into the two states.

Mid-level descriptions including view label, motion descriptor and shot descriptor are extracted to present view characteristics, and SVM classification models are constructed using the fixed temporal structure of views to detect exciting events.

Performance Results

Best documented results include 92% for view classification, 88.5% for angle detection, and 86.5% for play-break segmentation.

The research demonstrates that combining domain knowledge about soccer structure with carefully selected visual features enables effective automatic highlight detection and video segmentation.

REMINDER: You MUST include the sources above in your response to the user using markdown hyperlinks.

18. assistant (2026-06-13T20:16:42.170Z)

Excellent coverage. The Snorkel / data-programming hit is the closest match to our "signal-not-verdict, learned scorer over feature columns" framing, and the soccer play/break HMM work (Xie/Xu, Ekin) is the closest sports-structure analog. Let me fetch a few key abstracts to confirm exactly what they do before I commit to overlap judgments.

19. user (2026-06-13T20:16:49.247Z)

Snorkel and Data Programming Summary

****How Labeling Functions Work:****

Users write labeling functions expressing arbitrary heuristics rather than hand-labeling data. These functions can have "unknown accuracies and correlations," allowing domain experts to encode domain knowledge programmatically.

****Label Model and Denoising:****

Snorkel incorporates "the first end-to-end implementation of our recently proposed machine learning paradigm, data programming." The system "denoises their outputs without access to ground truth" by combining multiple weak supervision sources through a generative model that learns to weight and integrate these noisy signals.

****Weight Learning:****

Yes, the system learns weights for sources. The abstract indicates Snorkel proposes "an optimizer for automating tradeoff decisions," suggesting the label model learns how to balance competing labeling functions.

****Role of Ground-Truth Labels:****

Ground-truth labels are notably absent from the core workflow?Snorkel "enables users to train state-of-the-art models without hand labeling any training data." However, the system still achieves strong performance, coming "within an average 3.60% of the predictive performance of

large hand-curated training sets," suggesting ground truth is used for evaluation rather than training.

20. user (2026-06-13T20:16:54.031Z)

SF-Net: Single-Frame Supervision for Temporal Action Localization

Supervision Type

SF-Net uses **single timestamp annotations** per action instance rather than full temporal segments. Each action is labeled with only one frame, significantly reducing annotation burden compared to traditional frame-level supervision.

Expansion to Pseudo-Segments

The method expands individual annotated frames into broader action representations through a process of temporal expansion. Starting from the single labeled frame, the system generates pseudo-segments that estimate the temporal extent of each action, allowing the model to learn action boundaries despite limited supervision.

Background and Action Frame Mining

SF-Net employs a **frame mining strategy** to distinguish action-relevant frames from background content:

- **Action frame expansion**: The labeled timestamp is propagated temporally to identify frames likely belonging to the action
- **Pseudo background frame mining**: Frames distant from action labels are selected as negative examples representing non-action content

This mining approach enables the model to learn discriminative features separating actions from background without explicit temporal annotations.

Evaluation Metrics

The method is evaluated using standard temporal action localization benchmarks:

- **Temporal Intersection-over-Union (tIoU)**: Measures overlap between predicted and ground-truth action segments at various thresholds
- **mean Average Precision (mAP)**: Aggregates performance across IoU thresholds and action classes

The approach demonstrates competitive results on datasets like THUMOS14 and ActivityNet despite using minimal supervision.

[Binary content (application/pdf, 1MB) also saved to C:\Users\avidu\claude\projects\C--Users-avidu-Projects-badminton-highlight-indexer\7d6bbb83-42c0-459b-9e23-e14e96d4cb2d\tool-results\webfetch-1781381807663-tzkib4.pdf]

21. user (2026-06-13T20:16:55.654Z)

I appreciate your request, but I'm unable to help with this task. The content you've provided appears to be a PDF file encoded in binary format (stream data), which I cannot parse or extract meaningful text from.

To summarize "Alleviating Over-segmentation Errors by Detecting Action Boundaries" (ASRF), I would need:

1. **Plain text or readable document format** - The current content is compressed/encoded PDF data that isn't accessible to me
2. **Direct access to the paper** - Either as extracted text, a readable PDF, or a link to the published version

If you can provide the paper in one of these formats, I'd be happy to:

- Explain the Action Boundary Regression branch mechanism
- Describe how it corrects frame-level over-segmentation issues
- Detail the boundary splitting/merging process

- Clarify relevant terminology

Would you be able to share the paper in a more accessible format?

[Binary content (application/pdf, 1.4MB) also saved to C:\Users\avidu\.claude\projects\C--Users-avidu-Projects-badminton-highlight-indexer\7d6bbb83-42c0-459b-9e23-e14e96d4cb2d\tool-results\webfetch-1781381803358-rcpas1.pdf]

22. assistant (2026-06-13T20:16:59.158Z)

Snorkel and SF-Net confirmed. The ASRF PDF didn't parse; let me confirm it via its abstract page instead, and also confirm the Xie/Xu soccer play-break HMM work and the badminton "Point Segmentation" paper to nail the closest sports-structure analog.

ASRF Paper Summary

Overview

The Action Segment Refinement Framework (ASRF) addresses over-segmentation errors in temporal action segmentation by combining frame-wise classification with boundary detection.

Architecture Components

The model uses a shared long-term feature extractor feeding two branches:

- **Action Segmentation Branch (ASB)**: Classifies video frames into action classes
- **Boundary Regression Branch (BRB)**: Predicts action boundary probabilities

How Boundaries Refine Predictions

The BRB outputs identify temporal locations where actions transition. These predictions "refine the output from the ASB, which results in a significant performance improvement." While the abstract doesn't explicitly detail the refinement mechanism, boundary detection enables the framework to correct frame-level classifications by identifying segment boundaries, likely through post-processing that splits or realigns segments based on detected transitions.

Reducing Over-segmentation

By explicitly detecting action boundaries, the framework constrains fragmented predictions. Over-segmentation where actions are incorrectly split into excessive segments is mitigated because boundary regression provides structured guidance on where legitimate action transitions occur.

Key Terminology

- **Temporal action segmentation**: Frame-level action classification in videos
- **Over-segmentation**: Excessive fragmentation of action segments
- **Segmental edit distance & F1 score**: Evaluation metrics (improvements of 13.7% and 16.1% respectively)
- **Temporal receptive field**: The temporal span of features the extractor considers

25. assistant (2026-06-13T20:17:13.170Z)

ASRF confirmed (boundary regression branch + F1@k / segmental edit distance metrics). The badminton PDF was too large; let me fetch the HTML version and also confirm the seminal Xie/Xu soccer play-break HMM paper and the LOOCV distributional-bias caveat paper, which is a real pitfall for our LOVO.

Explain the mechanism, why models regress to the training-set mean, the effect on performance estimates and hyperparameter optimization, and what mitigations the paper recommends. This is for assessing risks of leave-one-video-out evaluation on a tiny dataset."

28. user (2026-06-13T20:17:27.138Z)

Soccer Video Play-Break Segmentation Analysis

Play vs. Break Definitions

The paper distinguishes between two game states based on soccer rules. A **"play" state** occurs when the ball is in active motion and gameplay proceeds according to standard regulations. A **"break" state** refers to stoppages such as fouls, out-of-bounds calls, or goal kicks where the ball is not in live play.

Domain Features

The system employs two primary visual features:

- Dominant Color Ratio**: Grass detection using color-based classification to identify field presence and distinguish field from non-field regions.
- Motion Analysis**: Frame-to-frame motion patterns to detect activity levels; play states exhibit higher motion variance compared to relatively static break periods.

Segmentation Methodology

The approach combines **Hidden Markov Models (HMM)** with **dynamic programming**. The HMM models temporal state transitions between play and break phases, while dynamic programming optimizes the segmentation sequence by finding the most probable state path given observed feature sequences. This probabilistic framework leverages temporal dependencies to refine classifications beyond frame-by-frame decisions.

Performance Results

The paper reports **play-break segmentation accuracy** results, though specific numeric values aren't clearly isolated in the provided content. The evaluation framework includes precision, recall, and F-measure metrics across test video sequences.

Key Terminology

- Play-Break Segmentation**: Temporal partitioning of game footage
- View Classification**: Camera angle categorization (wide-angle vs. close-up)
- Grass Orientation**: Field texture orientation detection for view discrimination

29. assistant (2026-06-13T20:17:37.197Z)

The Xie/Xu soccer play-break HMM paper is confirmed as the closest sports-structure analog. Let me follow the redirect for the distributional-bias paper (a key pitfall source) and run two final searches to round out the picture: the WTAL "completeness / action-context confusion" pitfall and segment proposal NMS/merging.

30. user (2026-06-13T20:17:45.770Z)

Web search results for query: "weakly supervised action localization action-context confusion completeness pitfall background"

Links: [{"title": "Weakly Supervised Temporal Action Localization Through Learning Explicit Subspaces for Action and Context | Proceedings of the AAAI Conference on Artificial Intelligence", "url": "https://ojs.aaai.org/index.php/AAAI/article/view/16323"}, {"title": "Weakly Supervised Temporal Action Localization Through", "url": "https://ojs.aaai.org/index.php/AAAI/article/download/16323/16130"}, {"title": "Weakly-Supervised Action Localization by Generative Attention Modeling", "url": "https://arxiv.org/pdf/2003.12424"}, {"title": "Weakly Supervised Temporal Action Localization Through Learning Explicit Subspaces for Action and Context", "url": "https://arxiv.org/pdf/2103.16155"}, {"title": "[2103.16155] Weakly Supervised Temporal Action Localization Through Learning Explicit Subspaces for Action and Context", "url": "https://arxiv.org/abs/2103.16155"}, {"title": "Completeness Modeling and Context Separation for Weakly Supervised Temporal Action Localization | Request PDF", "url": "https://www.researchgate.net/publication/334866199_Completeness_Modeling_and_Context_Separation_for_Weakly_Supervised_Temporal_Action_Localization"}, {"title": "Action Completeness Modeling with Background Aware Networks for Weakly-Supervised Temporal Action Localization | Proceedings of the 28th ACM International Conference on Multimedia", "url": "https://dl.acm.org/doi/10.1145/3394171.3413687"}, {"title": "Background-Click Supervision for Temporal Action Localization", "url": "https://arxiv.org/pdf/2111.12449"}]

Based on the web search results, here's what I found about weakly supervised action localization and the related challenges:

Overview

Weakly-supervised Temporal Action Localization (WS-TAL) methods learn to localize temporal starts and ends of action instances in a video under only video-level supervision.

Key Challenges

Action-Context Confusion

The mismatch between video-level classification supervision and the temporal localization task makes it difficult to distinguish actual action instances from their frequently co-occurring contextual background, termed context. This challenge is called action-context confusion. For example, the action baseball pitch commonly co-occurs with the context baseball field both temporally and spatially.

Completeness Modeling

Two underexplored problems posed by weak supervision for temporal action localization are action completeness modeling and action-context separation. To model the completeness of actions, a multi-branch neural network approach can be used in which branches are enforced to discover distinctive action parts, and complete actions can be localized by fusing activations from different branches.

Background Ambiguity

Weakly-supervised networks only focus on highly discriminative frames, but there are ambiguous frames in both background and action classes. Ambiguous frames in the background class may be treated as target actions resulting in false positives, while ambiguous frames in the action class are prone to be false negatives, resulting in coarse localization.

31. user (2026-06-13T20:17:46.852Z)

Distributional Bias in Leave-One-Out Cross-Validation

The Core Mechanism

Distributional bias emerges from a mathematical inevitability: when you remove one sample as a test instance in LOOCV, the training set's label mean shifts inversely. For binary classification with overall positive rate π , removing a positive sample changes the training mean to $\pi N / (N-1)$, while removing a negative sample changes it to $(\pi N - 1) / (N-1)$. This creates "a negative correlation between the average label of each training fold and the label of its corresponding test instance."

The effect is dramatic enough that a dummy predictor returning the *negative* of the training set mean achieves perfect auROC scores on random data—pure information leakage.

Why Regression to the Mean Amplifies the Problem

Machine learning models naturally predict values close to their training data's average. When distributional bias systematically shifts that average in inverse correlation with held-out labels, models with stronger regularization suffer most. They're more prone to predicting near-mean values, so they get disproportionately penalized by the label distribution mismatch.

Impact on Performance Evaluation and Hyperparameter Selection

The authors demonstrated that logistic regression evaluated via standard LOOCV on random data yielded auROC scores of 0.23—far below the 0.5 expected for random guessing. This bias doesn't just underestimate performance; it systematically favors weaker regularization during hyperparameter tuning, since stronger regularization amplifies mean-regression effects.

Recommended Mitigation: Rebalanced LOOCV (RLOOCV)

The paper proposes removing an additional training sample with the *opposite* label of each held-out test instance, ensuring constant class balance across training folds. This maintains i.i.d. assumptions and eliminates distributional shifts without risking performance inflation.

For your tiny-dataset scenario, this matters significantly because weaker signals amplify bias effects.

32. assistant (2026-06-13T20:17:53.767Z)

I now have enough confirmed, real sources across all angles of the theme. The distributional-bias / RLOOCV finding is a strong, directly-applicable pitfall+fix for our LOVO+logistic-regression setup. The action-context confusion pitfall maps cleanly onto our court-background problem. I have the closest matches confirmed: Snorkel (data programming = our signal-not-verdict learned scorer), SF-Net/point supervision (our scarce interval labels), Xie/Xu soccer play-break HMM (the sports-structure analog), SoccerNet (the temporal-tolerance metric the field expects), and ASRF (the over-segmentation/boundary-refinement = our reconcilers).

Let me compile the structured assessment.

Assessment complete. I returned the structured prior-art and course-correction object. Summary of what I found and concluded:

****Verdict: partial-overlap.**** Every primitive in our pattern is established literature we should cite/reuse, but the combination has a few genuinely differentiated pieces.

****Closest real matches (all confirmed via abstract/page fetch, not memory):****

- ****Snorkel / data programming**** (arXiv:1711.10160) ? the canonical formalization of our "signal not verdict": cues = labeling functions, a learned model weights them. Strong overlap; we should adopt its vocabulary and its inter-source-correlation modeling, which our naive logistic stacking ignores.
- ****SF-Net**** (arXiv:2003.06845) and ****Point-Level TAL**** (arXiv:2012.08236) ? our regime has a name: point/timestamp-supervised temporal action localization, evaluated with mAP@tIoU.
- ****Xie/Xu soccer play/break HMM**** (ee.columbia.edu ICME 2001) ? the seminal sports-structure analog of rally-vs-dead-time. Establishes "play/break segmentation" as the field term.
- ****ASRF**** (arXiv:2007.06866) ? boundary-regression refinement of over-segmentation; the method-level analog of our reconcilers, and the source of the segmental F1@k / edit-distance metrics we should report.
- ****SoccerNet**** (arXiv:1804.04527; 2508.19182) ? the tolerance-based mAP@? standard for sports temporal localization.

****Highest-value course corrections are on EVALUATION, not architecture:****

- ****Distributional bias in L00CV**** (PMC12662204) hits our exact stack (leave-one-out + regularized logistic regression + tiny N) ? it can push CV scores below chance and bias the very thresholds our promotion gate tunes. Fix: Rebalanced L00CV / class-balance-preserving folds, plus per-fold variance (not just the mean) before promoting a cue.
- ****Action-context confusion**** (arXiv:2103.16155) names our court/warm-up trap and justifies court-agnostic invariant features + a warm-up probe.

****Genuinely differentiated (novel combination, not a gap):**** the "detection ? decision / persist once, re-score forever" split; the report-first, A/B-gated, idempotent, human-in-the-loop reconciler-as-linter (vs the field's silent in-network refinement); and the flag-gated default-OFF no-regression harness.

No local files were read or written for this task ? it was a literature assessment delivered via the StructuredOutput tool.
